

Medical Debt in Collections

The case of Kentucky
by Sarah Weatherbee

Background

- As of 2019, Kentucky had the sixth highest poverty rate (17%) in the nation
- In 2019, The Lexington Herald Leader reported that 27 percent of Kentuckians “owe a collection agency for a combined \$1.5 billion in recent medical debt”
- Eastern Kentucky counties have the highest rate of people with medical debt in collections. I.e. Carter County: 52%
- Assumption: Medical debt sent to collections indicates unmanageable healthcare costs

Aims of this project

- Explore data on medical debt in collections in Kentucky by county
 - Is health insurance a protective factor?
 - Is income a protective factor?
 - Is there a relationship between overall debt in collections and medical debt in collections?
- Segment data by income level for a more detailed view of correlates
 - Low income = Less than \$43,717 (Less than 25th percentile of income)
 - Mid income = Between \$43,718 & \$58,199 (Between 25th and 75th percentiles of income)
 - High income = Greater than \$58,199 (Greater than 75th percentile of income)
- Map the burden of medical debt in collections by county

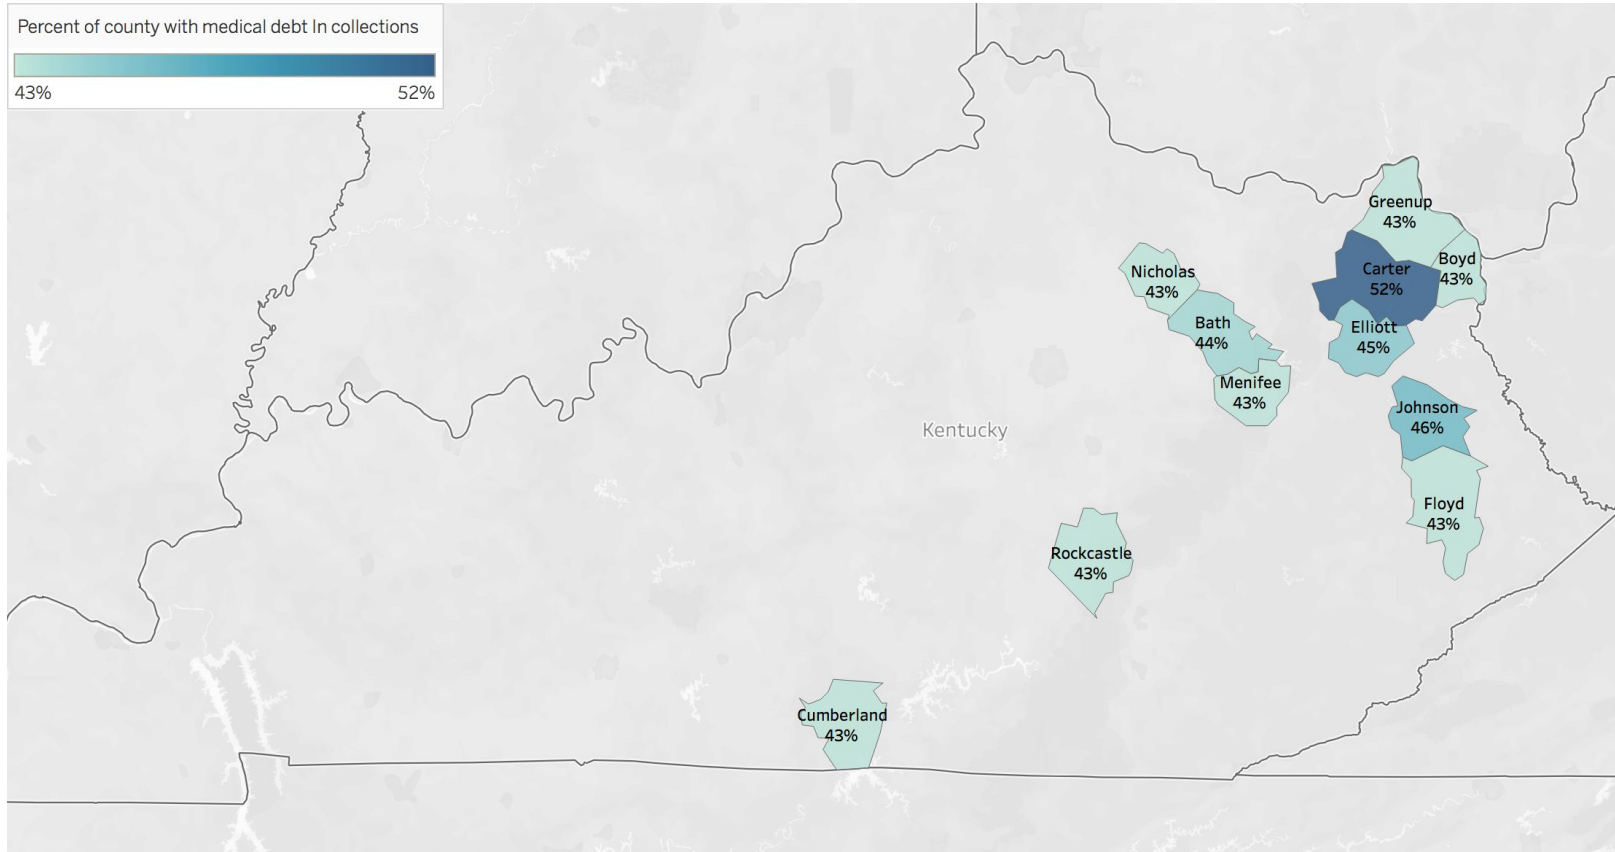

Data

- Debt in collections data and income data from the [Urban Institute](#):
 - This data “contains 2016 and 2017 data derived from a random sample of de-identified, consumer-level records from a major credit bureau as well as estimates from summary tables of the US Census Bureau’s American Community Survey”
- County population estimates 2017 from the [Kentucky State Data Center](#)

Where amount of medical debt in collections is highest

Where the most people have medical debt in collections

Meet Lenny of Carter County, Kentucky

Lenny was unemployed for several months, but now he has a job!

(And an affordable, but high deductible, insurance plan)

He slaughters pigs for Smithfield Foods.

His pay: \$15 per hour.
(\$31,200 per year)

Lenny recently wrecked his car and broke his leg

Now that he's employed and has health insurance, he will get through it. Or so he thinks...

The hospital fixed his leg and sent him a bill.

His insurance won't kick in until he pays his deductible: **\$1,500**

He will also have to pay **\$2,500**: The anesthesiologist for his surgery was out of network.

Now his bills are in collections

Lenny is still paying off debt from the several months he spent unemployed.

On his income, he can't keep up with payments on the hospital bill of **\$4,000**.

After not paying for three months, the hospital bill is sent to a collections agency.

The consequences

Because his bill was sent to collections, his credit score dropped.

This means he will have a hard time renting an apartment, buying a house, leasing a car, even getting a better job.

For Lenny and others like him, having health insurance does not mean that medical bills will be affordable.

Now, back to the data...

Overall Data

- There is a strong correlation between percent of county with debt in collections and percent of county with medical debt in collections
- For individuals such as Lenny who have debt in collections, Some or all of that debt is likely to be medical debt.

By income

The correlation between percent of county with debt in collections and percent of county with medical debt in collections is stronger at the middle and upper income levels

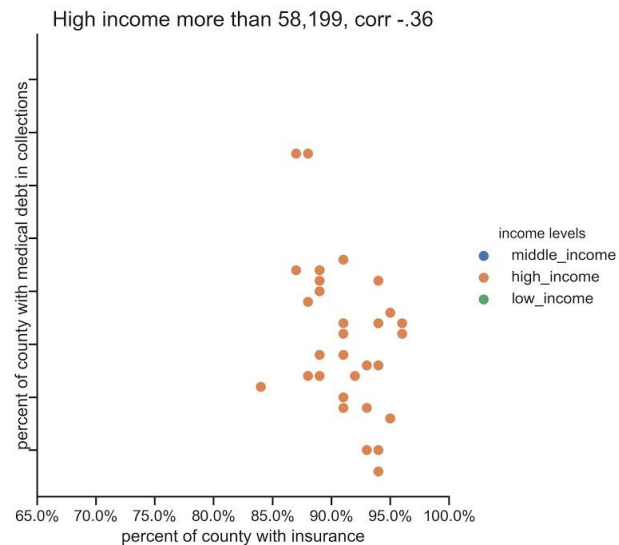

Overall Data

- There is a weak-moderate negative correlation between percent of county with medical debt in collections and percent of county with insurance
- ➔ As we saw with Lenny, insurance is not a strong protective factor against unaffordable medical bills

By income

The negative correlation between percent of county with medical debt in collections and percent of county with insurance approaches significance as income level rises

Overall Data

- There is a moderate negative correlation between percent of county with medical debt in collections and income.
- Those with lower incomes like Lenny are less likely to have a pricier insurance plan that helps keep medical bills manageable

By income

These plots show the relationship between income and the percent of county with medical debt in collections. It trends from a slightly positive relationship to a moderately negative one as income increases.

Tableau Dashboard

Outcomes

- I expected to find a relationship between the number of people with medical debt in collections and number of people with debt in collections, and I did. Correlation: .85.
- I expected to find a relationship between average income and number of people with medical debt in collections, and I did. Correlation: -.46

Outcomes Continued

- I expected to find a relationship between the number of people with health insurance and number of people with medical debt in collections, and I didn't find a strong one. The correlation was $-.39$
 - Broken down by income levels the correlations are not significant, but approach significance as income goes up
 - Low income correlation: $-.15$
 - Mid income correlation: $-.22$
 - High income correlation: $-.36$
- This suggests that insurance options for those at lower income levels do little to make healthcare costs manageable (i.e. high deductible plans that cost less but leave them paying more in the event of injury or illness)

Next Steps

- Obtain updated data from the Urban Institute
- Analyze the same data for other states
- Look closer at the top counties with the highest percent of people with medical debt in collections
 - Poverty rate
 - Health outcomes
 - Income inequality
 - Types of health insurance

APPENDIX

Notes/Limitations

- For counties with missing data, I replaced NaN's with the median value for that column.
 - Median debt in collections NaN's were replaced with 1295
 - Median medical debt in collections NaN's were replaced with 623
 - Percent of county with medical debt in collections NaN's were replaced with .29
- The debt data is from 2017 while the bankruptcy data is from 2019
- The data only offers a snapshot in time; I could not look at how characteristics have changed through the years
